ABSTRACT

Manganese is Nature's twelfth most abundant element and is considered as an strategic material. The world manganese ore reserves amount to more than one billion metric tons distributed in not more than a dozen countries being the most prominent: South Africa, Russia, Gabon, Australia, Brazil, India, China and Mexico.

An international manganese ore trade represented by imports and exports, has suffered a decrease in the last 8 years, as a consequence of the drop in the steel production and of its substitution for manganese ferroalloys by the main importing countries. As a result of the above, the manganese ore price has not moved up but actually decreased in real terms, for the past 7 years.

The manganese ore production capacity, without taking into consideration the Socialist Block, is estimated in around 15 million metric tons per year. The most outstanding manganese producers are: South Africa (7 million tons); Gabon (2.9 million); Australia (2.2 million); Brazil (2.3 million) and Mexico (0.7 million).

For the next 20 years the above countries will most probably to remain the main manganese ore suppliers of the western world.

The high carbon ferromanganese production is focused mainly in: Japan, South Africa, France, Norway and Germany. Other countries with a minor participation are: Australia, Canada, India, Brazil, Mexico and Spain. In the last years the production has shown a tendency to fall down as a consequence of a similar behavior observed in the steel production.

Ever since the high carbon ferromanganese production process was invented it has not undergone any significant modification, however, in the last 3 years a new process called plasma has been developed which, under specific conditions could partially displace the original process.

At the present time the supply of manganese ore as the main raw material is guaranteed with sufficient ore world reserves.

In the high carbon ferromanganese world trade, the largest export countries, are: France, South Africa and Norway with there other smaller exporting countries like: Canada, Mexico, Germany, Australia, Portugal and Brazil. Some others have vanished from the international markets as is the case of Japan, Italy and Spain. As far as ferromanganese imports is concerned, the United States of America has been the market where most of the exporting countries concur. In 1984 it represented 62% of the world total imports.

It is a conclusive factor for international competitiveness that certain natural comparative advantages exist in the different producing countries which make it possible their being as exporters: Such comparative advantages combined with the macro-economic and financial policies adopted by some producing countries, measured by the subvaluation of their currencies with respect to the North American dollar, has provided them with an additional competitive advantage thus enabling to ride well through the depressed market situation. Obviously these macro-policies affect the producers countries within operate the US dollar zones of influence.

Additionally, the drop in demand caused by the adverse economic situation suffered by the main industrial nations (which since the middle of the 1970's have seen their steel production volumes reduced) has worsened the manganese alloys price situation which since 1979, has practically remained on the same nominal level.

AVAILABILITY OF MANGANESE ORE IN THE WESTERN WORLD

Manganese is nature's twelfth most abundant element mainly in the form of oxides. The most important compounds are known as Pyrolusite, Rhodochrosite, Braunitz and Psylomelane.

Manganese is mainly used (95%) in the manufacture of steel. In the chemical industry it is used as fertilizer and fungicide. In the dry cell battery industry it is used mainly as a depolarizer.

Manganese is essential in the steel industry. It is used as an alloy element as well as a deoxidizing and desulfurizing agent. No substitute has been discovered to date and it can be used in the form of ferromanganese, silicomanganese, metallic manganese and directly as manganese ore.

Reserves

Even though manganese ore deposits exist at the bottom of the sea, the present economically exploitable reserves are located in the continental platform. Recognized manganese ore reserves, with Mn contents higher than 35%, are located in South Africa, Australia, Gabon, Brazil, India and China. Manganese ore reserves with lower Mn content are found in Mexico and Ghana.

Apparent Ore Consumption (Table 2)

The apparent consumption by the steel industry on which the manganese production is based, has shown a decrease of 12.2% from 1980 to 1985, due mainly to the behavior of the steel industry.

In the last six years, the manganese unit consumption per ton of steel has decreased 3.4% annual average.

Manganese Ore Production (Table 3)

The present manganese ore annual production capacity amounts to 31.0 million tons, concentrated mainly in the Soviet Union, South Africa, Brazil and Australia.

Manganese ore mining is performed largely through highly-mechanized open pit operations and from underground mines by means of traditional mining techniques.

The metallurgical processes employed by producers which ore reserves have a low manganese content includes not only ore crushing screening and washing but also highly elaborated systems such as sink float, jigging, tabling and flotation.

Nodulizing, sintering and pelletizing method are being used to semireduce and to agglomerate the ore. Rotary kilns are used for roasting and nodulizing the manganese ore carbonates.

Those producers holding high-grade manganese ore reserves compare advantageously in cost over those which own lower grade manganese ore reserves which require other treatment than crushing, screening and washing representing additional costs.

Manganese Ore Production (Table 4)

Production is divided between the Western world (55%) and the Socialist Block (45%).

From the total production, 51% corresponds mainly to South Africa, Gabon, Australia, Brazil, Mexico and India and 44% is concentrated mainly in the Soviet Union and China.

The annual average manganese production growth in the last years was a negative 3.4% which is coincident with the steel industry behavior.

Imports Manganese Ore (Table 5)

Manganese ore imports have shown a very unstable behavior tending to take a downwards direction. From 1980 to 1985 an average negative growth rate of 3.3 per year was observed.

Japan has been the leading manganese importing country in the last 6 years, having imported 33% of the total manganese imports in 1985, followed by France with 15%. As far as manganese ore import transactions per country is concerned, the U.S.A. has been distinguished for having decreased its imports from 1980 to 1985 to by an average annual rate of 11% which is higher than the drop in the steel production which amounted to 3.8% within the same period. West Germany follows with a decrease of 6.7% on its manganese ore imports, calculated as an average annual rate while its steel production decreased by 1.3% in the same period.

Exports of Manganese Ore

Exports performed similarly to imports, having obtained in general terms, from 1980 to 1985, an annual average growth rate of only 0.3%.

Market Share

As can be observed from the preceding Tables, there are only a few countries which supply the demands of the manganese world market and their market share evolution is shown in the Table 7.

The relative importance of the suppliers of the first exporting four countries (South Africa, Gabon, Australia and Brazil) raises a question of substance: Whether anyone of these countries could take the place of other any in case of emergency.

At present, Australia has an annual production capacity of 2.2 million tons of manganese ore which could be increased to 3.0 million; however, this expansion project has been temporarily suspended. South Africa has a production capacity of 7.0 million tons of manganese per year; in 1985 the utilization capacity was only 40%. Gabon's production capacity amounts to 2.9 million tons per year which could be easily increased to 4 or 5 million tons provided, however that the railroad construction is completed. Brazil could increase its manganese exports to the same volumes obtained in preceding years.

Therefore, the production of any of the countries mentioned above, could be readily substituted in order to continue supplying in a short term the manganese ore demand although additional investments would be required.

Now, based on constant dollars, manganese prices have suffered up to 1985 a real decrease of 38% with respect to the 1978 prices, and 69% with respect to the prices prevailing in 1960.

Manganese Resources and Reserves
The Economics of Manganese

From the foregoing it can be affirmed that the manganese production has maintained a behavior similar to that of the steel production and that notwithstanding that the manganese unit demand has decreased the total demand will continue growing only at the same rate as the manganese ferroalloys productions grows.

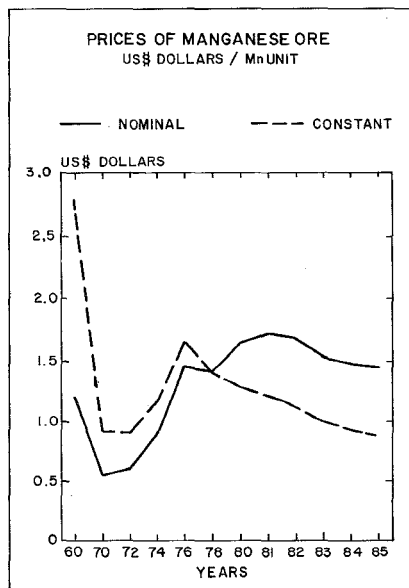

The depression in the manganese price reflects the large manganese oversupply and the highly aggressive marketing strategies followed by the leading exporting countries.

Prices of Manganese Ore (Graph 8)

Manganese ore prices are established principally through direct negotiations between seller and buyer, which include: amount, delivery terms, chemical analysis, manganese content, etc.

At the end of 1986, the price of 1.42 US\$ per long ton unit was at the same nominal level as in 1976.

GRAPH 8

Production Capacity of H.C. Ferromanganese (Table 9)

The world manganese ferroalloys production capacity is estimated in about 8.0 million metric tons per year of which 1.5 million tons are produced by the Socialist Block. The above production is divided accordingly to the following percentages:

| | |
|--------------------------------------|------|
| HIGH CARBON FERROMANGANESE | 64% |
| MEDIUM AND LOW CARBON FERROMANGANESE | 10% |
| SILICOMANGANESE | 26% |
| TOTAL CAPACITY | 100% |

Production of H.C. Ferromanganese (Table 10)

The high carbon ferromanganese production which represents 64% of the total capacity, consumes 70 to 75% of the total manganese ore used in the ferroalloys production.

High-carbon ferromanganese can be produced either in blast furnace or in electric furnace. At the present time, 85 to 90% of the world high-carbon ferromanganese is produced in electric furnaces. Two main advantages are obtained by the electric furnace:

1. They can be installed in medium sized unit thereby reducing capital investment.
2. They have the ability to use the slag from high-carbon ferromanganese production in the production of silicomanganese.

In the last 3 years a new process called plasma, has been developing, which consequently, under specific conditions could have a main contribution in the high carbon ferromanganese production in the years to come.

As may be observed in Table 10 in 1969 the principal ferromanganese producing countries were also the main steel producing centers, since the ferromanganese production was projected towards supplying the domestic demand. However, in the last 20 years, this pattern has drastically changed and the production is now focused mainly in Norway, South Africa, France, Germany, Mexico, Canada and India, some of which are also strong exporters.

The Economics of Manganese

The present tendency towards producing ferromanganese and other ferroalloys in general, is centered in those countries holding natural comparative advantages (Table 12) such as: Cheap electric power available (Brazil and Norway own enough hydroelectric plants); manganese ore and raw material availability (South Africa, Mexico, Brazil and Australia), and relatively cheap labor availability (South Africa, Mexico and Brazil).

This tendency in the ferromanganese production is very similar to the one observed in the manganese ore production; that is, the production capacity is being increased mainly in those countries possessing important manganese ore deposits and large manganese ore production capacity.

Consumption of H.C. Ferromanganese (Table 13 and 14)

With respect to ferromanganese consumption it may be observed from the Table 13, that in general terms, it is decreasing since it has been affected by two significant factors:

- a) Reduction in the steel production and,
- b) Optimizing of ferromanganese use; which brings as a consequence a decrease in the unit consumption per ton of steel produced.

With respect to ferromanganese imports, in the last 15 years it has been observed that imports have been centered in the main steel producing countries such as: United States, Germany, United Kingdom and Italy.

Exports of H.C. Ferromanganese (Table 16)

As mentioned in preceding paragraphs, the ferromanganese exports have become more relevant from countries which have control over enormous manganese ore deposits. In addition, the comparative advantages of the ferromanganese producing countries are becoming a determinant factor for international market competition.

It is expected that this tendency continues in the next years.

Prices of H.C. Ferromanganese (Graph 17)

As a consequence of the combined effect of the depressed steel production prevailing in the Western countries in the recent past which reduced its volume at an annual average rate of 1% during the last six years, the supply of High Carbon Ferromanganese has been superior to its demand, thus resulting in a drastic decrease of its nominal price by as much of 22% from 1979 to 1985. The constant price since 1978 has decreased by 45% in the same period. Graphic 17 shows that the ferromanganese price in 1985 is 25% lower than the price obtained in 1979.

A very aggressive marketing policy is being followed at the present time by the main ferro-alloy producers which primary consequence is the depression observed in the international markets.

In addition, the macro economic and financial policies adopted by several countries measured by the subvaluation of their currencies with respect to the U.S. dollar, allows them an additional competitive price advantages depending on the amount of their subvaluation level.

CONCLUSIONS

It is unquestionable that manganese is an essential element for the steel industry and that as a consequence the manganese production has maintained and will continue maintaining a similar behavior to that of the steel production. Notwithstanding that the unit consumption has decreased, the total demand will continue growing, though at a less accelerated rythm.

The general tendency implies a concentration of the manganese ore and ferromanganese production and marketing in those countries possessing large manganese ore deposits and energy, labor and raw materials as natural comparative advantages.

The manganese ore and manganese alloy depressed prices are caused by the unbalance of excess production capacity related to lower demand, combined with aggressive marketing strategies conducted by the mayor manganese alloy producers.

Now that the currëncies are starting to adjust their parities to more realistic terms of interchange in relation to the U.S. Dollar, it is quite probable that the near term will see a strengthening of the market prices of Manganese ferroalloys, which is long overdue. It is also probable that South Africa and France after having established a sound share of the U.S. market, their producers will benefit from higher prices eventhough the currëncies and specially the Rand could contirue undervalued.
